UPLINK SCRAMBLING CODE ASSIGNMENT
FOR A RANDOM ACCESS CHANNEL

This application claims priority from U.S. Provisional Application No. 60/134,880, filed May 19, 1999.

BACKGROUND

The invention relates generally to resource allocation in a wireless code division multiple access (CDMA) communication system. More specifically, the invention relates to assigning uplink scrambling codes in a CDMA communication system.

Figure 1 depicts a wireless spread spectrum Code Division Multiple Access (CDMA) communication system **20**. A base station **22** communicates with user equipment (UE) **24₁-24_n** in its operating area. In a spread spectrum CDMA system **20**, data signals are communicated between UEs **24₁-24_n** and the base station **22** over the same spectrum. Each data signal in the shared spectrum is spread with a unique chip code sequence. Upon reception, using a replica of the original chip code sequence, a particular data signal is recovered.

Since signals are distinguished by their chip code sequences (code), separate dedicated communication channels are created using different codes. Signals from the base station **22** to the UEs **24₁-24_n** are sent on downlink channels and signals from the UEs **24₁-24_n** to the base station **22** are sent on uplink channels. For coherent detection of downlink

transmissions by the UEs 24_1-24_n , pilot signals are transmitted to all of the UEs 24_1-24_n within the base station's operating range. The UEs 24_1-24_n condition their receivers based on the pilot signals to enable data reception.

In many CDMA systems, a random access channel, such as the common packet channel (CPCH), is used for some uplink transmissions. A CPCH is capable of carrying packets of data from different UEs 24_1-24_n . Each packet is distinguishable by its code. For detection by the base station **22**, the packets have a preamble which also distinguishes it from other packets. The CPCH is typically used to carry infrequently communicated data at high rates.

Figure 2 illustrates a CPCH time slot and frame structure. The CPCH structure is time divided into radio frames 30_1-30_m having time slots 28_1-28_n , such as eight time slots proposed for the Third Generation Mobile Telecommunications System (IMT-2000)-UMTS. A radio frame 30_1-30_m in IMT-2000 is 10 milliseconds in duration and each time slot is 1.25 ms. The radio frames 30_1-30_m are grouped into superframes **32**. Each superframe **32** has a fixed number of radio frames 30_1-30_m , such as 72 radio frames in IMT-2000.

To allow more than one UE 24_1-24_n to use a given time slot 28_1-28_n , multiple signatures are used to distinguish the UEs 24_1-24_n . In IMT-2000, sixteen different signatures are used. A particular signature used within a particular time slot is referred to as an access opportunity. **Figure 3** illustrates the access opportunities $26_{11}-26_{mn}$ of the CPCH. For instance, as proposed for IMT-2000, for each of the 8 time slots, one out of 16

signatures is available to be chosen, resulting in 128 access opportunities. Each access opportunity 26_{11} - 26_{mn} is preassigned an uplink scrambling code. The scrambling code is a function of the time slot T_K and the signature S_K that the UE used for access. Accordingly, the uplink scrambling code, C_K , is a function of the time slot, T_K , and signature, S_K , of the access opportunity 26_{11} - 26_{mn} as in Equation 1.

$$C_K = 8 * T_K + S_K \quad \text{Equation 1}$$

The UE 24_1 transmits a data packet using a selected access opportunity 26_{11} - 26_{mn} . Upon identifying a particular access opportunity 26_{11} - 26_{mn} , the base station 20 sends out an acknowledgment message (ACK) if the corresponding scrambling code is available. The ACK message may be one of several types, such as simply being a downlink transmission of the signature associated with the UE's access attempt. If the scrambling code is not available, a negative acknowledgment (NAK) is sent. After receiving the appropriate ACK message, the UE 24_1 selects the proper uplink scrambling code to transmit the packet data on the CPCH. If the UE 24_1 receives a NAK, it will re-attempt access by transmitting another packet.

This approach for assigning uplink scrambling codes has drawbacks. A typical scrambling code is only 10 ms in length. A transmitted data packet may last more than one radio frame 30. Since a data packet may last for multiple radio frames, the scrambling code used for that packet can only be reassigned after the transmission of that packet is complete.

As a result, the number of CPCH users is limited by the number of scrambling codes assigned to the access opportunities 26_{11} - 26_{mn} , such as 128 scrambling codes. Additionally, if a second user uses the same access opportunity 26_{11} - 26_{mn} as an already transmitting first user, the second user will receive a NAK. Repeated negative access attempts lower the efficiency of the system 20 which is undesirable.

Accordingly, it is desirable to use alternate scrambling code assignment schemes.

SUMMARY

A user equipment transmits a data packet using a selected signature in a time slot of a radio frame within a superframe of a common packet channel. The superframe being time divided into radio frames. A base station identifies the selected signature, transmission time slot and transmission radio frame of the data packet. The base station determines an uplink scrambling code for the user equipment based on in part the identified signature, transmission time slot and transmission radio frame. The base station selectively transmits an acknowledgment message based on in part an availability of the determined uplink scrambling code. The user equipment receives the acknowledgment message and transmits a subsequent data packet using the determined uplink scrambling code.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is an illustration of a typical wireless spread spectrum CDMA

communication system.

Figure 2 is an illustration of the time slots, radio frames and superframes of the random access channel.

Figure 3 is an illustration of a random access channel access scheme.

5 **Figure 4** is a flow chart of uplink scrambling code assignment.

Figure 5 is a simplified base station and user equipment.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

10 **Figure 4** is a flow chart of uplink scrambling code assignment. To initiate communications with the base station **22**, a UE **24₁** transmits a data packet over the random access channel, such as a CPCH. The packet is transmitted with a selected access opportunity **26₁₁-26_{mn}**. The selected access opportunity **26₁₁-26_{mn}** is defined by its signature and time slot in a radio frame **30₁-30_m**. The UE **24₁** also knows which radio frame **30₁-30_m** within the superframe and access opportunity **26₁₁-26_{mn}** the packet was transmitted, **34**. For
15 instance, in a system **30₁-30_m** having a superframe **32** of seventy-two radio frames **30₁-30_m**, an access opportunity **26₁₁-26_{mn}** using code 2 in time slot 4 sent in the twentieth radio frame in the superframe sequence is known by the UE **24₁**.

The base station **22** identifies the access opportunity **26₁₁-26_{mn}** and the radio frame **30** within the superframe **22** in which the packet was transmitted, **36**. The uplink scrambling
20 codes are assigned based on a function of the selected access opportunity **26₁₁-26_{mn}** and

radio frame 30_1-30_m used by the UE 24_1 for the packet as in **Equation 2, 38**.

$$C_K = g(F_K, T_K, S_K) \quad \text{Equation 2}$$

F_K is the transmitted packet's radio frame 30_1-30_m within the superframe **32**. Using **Equation 2**, the number of uplink scrambling codes that may be assigned is dramatically increased. For a system using eight time slots, sixteen signatures and seventy-two radio frames within the superframe **32**, the possible uplink scrambling code assignments increases from a maximum of 128 to 9,216. By increasing the available scrambling codes, the number of users capable of utilizing the CPCH is increased. Although increasing the number of available scrambling codes is desirable, it has drawbacks. The codes available to the system **20** is a limited resource and should be allocated conservatively.

One approach to limit the available scrambling codes with no or a negligible decrease in the number of users is to reassign codes after a number of radio frames 30_1-30_m . Some packets may last more than a single radio frame. However, the packet length typically does not exceed a certain number of radio frames 30_1-30_m . Additionally, based on the system **20**, the packet length may also be limited as a system parameter. A typical limitation for an IMT-2000 system would be eight radio frames. Since the packet duration is limited or the duration typically does not exceed a limit, the uplink scrambling codes may be repeated after a specified number of radio frames, the limit, L . The limit, L , may be a system design parameter. The limit, L , may also be broadcast or transmitted to the UEs 24_1-24_n at call setup or on a periodic basis.

For a system using a radio frame limit of L, **Equation 3** is a function for such an uplink scrambling code assignment.

$$C_K = g ((F_K)_L, T_K, S_K) \quad \text{Equation 3}$$

$(\cdot)_L$ denotes a modulus-L operation. As a result, the uplink scrambling code assignments are repeated every L radio frames. Since no packets or a negligible number of packets exceed the frame limit, L, the number of users using the CPCH is not reduced.

For a system using an eight radio frame limit ($L = 8$), **Equation 3** becomes **Equation**

4.

$$C_K = g ((F_K)_8, T_K, S_K) \quad \text{Equation 4}$$

Using **Equation 4** in a 16 signature, 8 time slot system, the maximum number of assignable uplink scrambling codes is reduced to 1,024. Using **Equations 3** or **4** and the limit, L, the number of necessary uplink scrambling codes is kept to a low level with the number of potential users being increased dramatically.

Using either **Equation 3** or **4**, the base station **22** determines whether the scrambling code associated with the UE's access attempt is available, **40**. If that uplink scrambling code is not available, a NAK message is sent to the UE **24₁**, **42**. After receiving a NAK message, the UE **24₁** will reattempt access, **44**.

If the determined uplink scrambling code is available, the base station **22** transmits

an ACK message to the UE 24₁, 46. Subsequently, the UE 24₁ will transmit packet data using the uplink scrambling code associated with the UE's access attempt.

Figure 5 illustrates a simplified base station 22 and a UE 24₁ for use in implementing uplink scrambling code assignment. The UE 24₁ has a controller 60 for determining the scrambling code of the uplink data packets. A UE transmitter 58 sends uplink data packets to the base station 22 based on the determined scrambling code. A UE receiver 56 receives communications from the base station 22.

The base station 22 has a controller 50 for determining the scrambling code of the uplink data packets. A base station transmitter 52 sends communications to the UE 24₁. The base station receiver 54 receives uplink data packets from the UE 24₁ using the determined scrambling code.

CLAIMS

What is claimed is:

1. A method of assigning uplink scrambling codes for use by a user equipment in transmitting packet data over a random access channel in a code division multiple access system, the random access channel being time divided into super frames having a set of radio frames, each radio frame is time divided into a set of time slots, the method comprising:

5 transmitting from the user equipment an access data packet using a selected signature out of a set of signatures and in a time slot of a radio frame;

identifying at a base station the selected signature, the transmission time slot and the transmission radio frame of the access data packet;

10 determining at the base station an uplink scrambling code for the user equipment based on in part the identified signature, transmission time slot and transmission radio frame;

selectively transmitting from the base station an acknowledgment message based on in part an availability of the determined uplink scrambling code; and

receiving the acknowledgment message at the user equipment and transmitting a subsequent data packet using the determined uplink scrambling code.

2. The method of claim 1 further comprising if the determined uplink scrambling code is unavailable, transmitting a negative acknowledgment to the user equipment.

3. The method of claim 1 wherein the superframes have a set of 72 radio frames and each radio frame is divided into a set of eight time slots.

4. The method of claim 3 wherein the set of signatures numbers sixteen.

5. The method of claim 1 wherein the determined scrambling code is based on a function of the identified signature, transmission time slot and transmission radio frame.

6. The method of claim 1 wherein the random access channel is a common packet channel.

7. A method of assigning uplink scrambling codes for use by a user equipment in transmitting packet data over a random access channel in a code division multiple access communication system, the random access channel being time divided into time slots, the method comprising:

5 defining a maximum number L of sequential time slots over which a specific data packet can be transmitted;

defining a set of N predetermined scrambling codes for the common packet channel where $N > L$; and

defining an association of the scrambling codes based on in part time slots, such that

10 when one of the scrambling codes is associated with a specific time slot, the next L time slots are associated with different scrambling codes.

8. The method of claim 7 wherein L is a system design parameter and no packet may exceed L time slots.

9. The method of claim 7 wherein L is a number of time slots typically not exceeded by a data packet.

10. The method of claim 7 wherein L time slots contains a set number of sequential radio frames, each radio frame having a set number of time slots.

11. The method of claim 10 wherein the set number of sequential radio frames is eight and the set number of time slots in each radio frame is eight.

12. The method of claim 7 wherein the defined association repeats every L time slots.

13. The method of claim 7 wherein the random access channel is a common packet channel.

14. A code division multiple access communication system using a random access channel for communication, the random access channel being time divided into super frames having a set of radio frames, each radio frame is time divided into a set of time slots, the system comprising:

5 a user equipment having:

means for transmitting an access data packet using a selected signature out of a set of signatures and in a time slot of a radio frame; and

means for receiving an acknowledgment message and transmitting a subsequent data packet using a determined uplink scrambling code; and

10 a base station having:

means for identifying the selected signature, the transmission time slot and the transmission radio frame of the access data packet;

means for determining the uplink scrambling code for the user equipment based on in part the identified signature, transmission time slot and transmission radio frame;

15 and

means for selectively transmitting an acknowledgment message based on in part the identified signature, transmission time slot and transmission radio frame; and

means for selectively transmitting an acknowledgment message based on in part an availability of the determined uplink scrambling code.

15. The system of claim 14 further comprising means for transmitting a negative acknowledgment to the user equipment, if the determined scrambling code is unavailable.

16. The system of claim 14 wherein the superframes have a set of 72 radio frames and each radio frame is divided into a set of eight time slots.

17. The system of claim 16 wherein the set of signatures numbers sixteen.

18. The system of claim 14 wherein the determined scrambling code is based on a function of the identified signature, transmission time slot and transmission radio frame.

19. The system of claim 14 wherein the random access channel is a common packet channel.

20. A controller for assigning scrambling codes for packet data being transferred over a channel in a wireless code division multiple access communication system, the channel being time divided into time slots, the controller comprising:

means for defining a maximum number L of sequential time slots over which a specific data packet can be transmitted;

means for defining a set of N predetermined scrambling codes for the channel where

$N > L$; and

means for defining an association of the scrambling codes based on in part time slots, such that when one of the scrambling codes is associated with a specific time slot, the next

10 L time slots are associated with different scrambling codes.

21. The controller of claim 20 wherein the controller is used by a base station to assign uplink scrambling codes.

22. The controller of claim 20 wherein the controller is used by a user equipment to determine a scrambling code for uplink communications.

23. The controller of claim 22 wherein the uplink communications are data packets and the channel is a common packet channel.

24. The controller of claim 20 wherein L is a system design parameter and no packet may exceed L time slots.

25. The controller of claim 20 wherein L is a number of time slots typically not exceeded by a data packet.

26. The controller of claim 23 wherein L time slots contains a set of sequential radio frames, each radio frame having a set number of time slots.

27. The controller of claim 26 wherein the set number of sequential radio frames is eight and the set number of time slots in each radio frame is eight.

28. The controller of claim 20 wherein the defined association repeats every L time slots.

ABSTRACT

A user equipment transmits a data packet using a selected signature in a time slot of a radio frame within a superframe of a random access channel. The superframe being time divided into radio frames. A base station identifies the selected signature, transmission time slot and transmission radio frame of the data packet. The base station determines an uplink scrambling code for the user equipment based on in part the identified signature, transmission time slot and transmission radio frame. The base station selectively transmits an acknowledgment message based on in part an availability of the determined uplink scrambling code. The user equipment receives the acknowledgment message and transmits a subsequent data packet using the determined uplink scrambling code.
